**METHOD AND APPARATUS FOR CONTENT-BASED SPEED VARIATION OF AN OPTICAL  
STORAGE DRIVE**

**FIELD OF THE INVENTION**

[0001] This invention relates generally to optical storage drives, and more specifically, to reducing the power consumption of such devices.

**BACKGROUND OF THE INVENTION**

[0002] A major emphasis of mobile computing system (MCS) development is to increase battery life without increasing the battery size. This can be done by decreasing the energy consumption of the MCS. The optical storage drive of a MCS is high on the list of energy consuming components (the display screen and the hard drive, being perhaps the only worse offenders). A compact disc (CD) drive or a digital versatile disc (DVD) drive may consume up to 20% of a system's energy.

[0003] There are many optical storage disk formats including CD audio, CD-R, CD-RW, DVD-RAM, DVD-ROM, and DVD-video. These disks can be read at different rates. Optical storage drives having various drive speeds have been developed with the drive speeds usually designated in reference to a base multiplier X. The base multiplier represents the time it took to read data from a CD in its original format, which was 150 kilobytes per second (kbps). Therefore a 1X drive speed accommodated a data transfer rate of 150 kbps, a 2X drive speed accommodated a data transfer rate of 300 kbps, etc. A 1X drive speed corresponds to the disc spinning within the drive at between 200 and 500 RPMs. CDs with successively faster data transfer rates have been developed. Optical

storage drives to accommodate these data transfer rates may have drive speeds of 12X, 24X or 52X. These drive speeds may correspond to proportionately higher disk rotational speeds. For example an 8X drive speed may spin the disk within the drive at between 1600 and 4000 RPMs. Some storage media such as DVD may be much denser than a CD, and therefore, be able to transfer data at much higher rates without a proportional increase in disk rotational speed.

[0004] Many optical storage drives are designed to support reading from various types of optical storage media. For example, MultiRead, MultiRead2, and Multiplay are Optical Storage Technology Association (OSTA) designations for devices that can read multiple formats such as DVD-ROM, DVD-Video, CD, CD-R, CD-RW, and others. These devices are typically fixed speed, with that speed corresponding to the highest speed that may be required for applications that the device supports. These devices may therefore spin disks much faster than required for a particular content of a disk. For example, a Multiplay device that is reading an audio CD may spin the disk at the same speed as if it were reading DVD-video. Therefore energy is being consumed to keep the audio CD spinning at a rate that may be many times faster than required to transfer audio CD data. The disk is rotating at a high rate, but only being accessed periodically as required to read the audio data.

[0005] An optical storage drive typically consumes a relatively large amount of energy to get the disk rotating at a given speed, after which the energy consumption is dependent to a large extent on the speed at which the disk is rotating.

[0006] **Figure 1** illustrates energy consumption for reading DVD-Video at, for example 12X, as compared to reading an audio CD at, for example 1X. Graph 105 shows

the energy consumption for a DVD. At  $t_0$  the disk is at rest, as illustrated there is some energy consumption associated with holding the disk at rest. At  $t_1$  there is a surge in energy consumption to get the disk rotating at the desired speed. This surge is known as in-rush current and may spike as high as 3.5 watts. After the disk is rotating, at  $t_2$ , there is a steady consumption of energy that may be approximately 0.75 watts. At  $t_3$  the disk returns to rest. Graph 110 shows the energy consumption for a CD audio. As shown, graph 110 has similar characteristics to that of 105, but uses less energy. At  $t_1$  the surge in energy consumption may be less than 3.5 watts. In general it may take almost as much energy to get the disk spinning, but the energy required to keep the disk rotating at a slower speed may be significantly less. For example, a speed of 1X may require only approximately 0.25 watts to maintain.

[0007] More energy is required to get the disk rotating at a higher speed and to keep it rotating at a higher speed. Therefore, Multiplay devices may consume more energy than necessary by rotating a disk at a higher speed than necessary.

## **BRIEF DESCRIPTION OF THE DRAWINGS**

[0008] The present invention is illustrated by way of example, and not limitation, by the figures of the accompanying drawings in which like references indicate similar elements and in which:

[0009] **Figure 1** illustrates energy consumption for a DVD and an audio CD in accordance with the prior art;

[0010] **Figure 2** illustrates an exemplary computing system for implementing one embodiment of the present invention;

[0011] **Figure 3** illustrates a process flow diagram in accordance with one embodiment of the present invention; and

[0012] **Figure 4** is a block diagram of an optical storage drive system in accordance with one embodiment of the present invention.

## **DETAILED DESCRIPTION**

[0013] One embodiment of an optical storage drive reduces energy consumption by ascertaining the file type to be read and rotating the optical disk at a reduced speed based upon the file type. In one embodiment the optical storage device contains a drive-speed lookup table stored in a memory. The file type is used to index the table to obtain a corresponding drive speed. In one embodiment a coded speed is input into the motor control hardware register to limit the drive voltage thereby limiting the drive speed.

[0014] In the following detailed description, numerous specific details are set forth to provide a thorough understanding of the present invention. However, it will be apparent to one skilled in the art that the present invention may be practiced without these specific details. In some instances, well-known structures and devices are shown in block diagram form, rather than in detail, in order to avoid obscuring the present invention.

[0015] **Figure 2** illustrates an exemplary computing system 200 for implementing one embodiment of an optical storage drive having a content-based drive-speed variation capability in accordance with the present invention. The multi-speed optical storage drive, the drive speed lookup table, and the motor control hardware registers described herein can be implemented and utilized within computing system 200, which can represent a MCS (e.g., a notebook computer), a general-purpose computer, or other like device. The components of computing system 200 are exemplary in which one or more components can be omitted or added. For example, one or more memory devices can be utilized for computing system 200.

system 200 can interface with display 221 via display circuit 205. Keypad input 222 is a alphanumeric input device with an analog to digital converter. Cursor control 223 can be, e.g., a mouse, a trackball, or cursor direction keys, for controlling movement of an object on display 221. Hard copy device 224 can be, e.g., a laser printer, for printing information on paper, film, or some other like medium. A number of input/output devices 225 can be coupled to computing system 200. An optical storage drive having a content-based drive speed variation capability in accordance with the present invention can be implemented by hardware and/or software contained within computing system 200. For example, CPU 202 or signal processor 203 can execute code or instructions stored in a machine-readable medium, e.g., main memory 204.

[0020] The machine-readable medium may include a mechanism that provides (i.e., stores and/or transmits) information in a form readable by a machine such as computer or digital processing device. For example, a machine-readable medium may include a read only memory (ROM), random access memory (RAM), magnetic disk storage media, optical storage media, flash memory devices. The code or instructions may be represented by carrier-wave signals, infrared signals, digital signals, and by other like signals.

[0021] **Figure 3** illustrates a process flow diagram in accordance with one embodiment of the present invention. Process 300, shown in **Figure 3**, begins with operation 305 in which the device driver of an optical storage drive receives a command to read a file. The file type is included in the command.

[0022] At operation 310 a drive-speed lookup table is accessed. The drive-speed lookup table contains several coded drive-speeds corresponding to different file types. In

one embodiment, a given speed corresponds to several file types of differing optical storage format. In an alternative embodiment each file type uniquely corresponds to a given speed.

[0023] At operation 315 a coded drive speed corresponding to the file type is obtained. For example, a file type of audio CD may correspond to a drive speed of 1X while a file type of DVD-ROM may correspond to a speed of 12X.

[0024] At operation 320 the coded drive speed is used to set the drive speed based on file type, as appropriate. In one embodiment the coded drive speed may be used to set the voltage supplied to the drive and thereby set the drive speed.

[0025] **Figure 4** is a block diagram of an optical storage drive system in accordance with one embodiment of the present invention. System 400, shown in **Figure 4**, includes an optical storage device driver 405 coupled to an optical storage drive controller 410. The device driver 405 receives a command to read a file from, for example, a CPU, not shown. This command contains the file type that may be for example audio CD or DVD-RAM. The device driver 405 passes the file type to drive controller 410 as an index, for example, audio CD may have an index of 1 and DVD-RAM may have an index of 12. The drive controller accesses coded drive-speeds 415. The coded drive speeds 415 contain an indexed list of coded speeds. The coded drive speeds 415 may be stored in firmware that may be, for example, an EEPROM. The drive controller 410 may provide an index to the EEPROM that allows the drive controller 410 to read a specific location of the EEPROM containing a coded drive-speed. The index may correspond to a specific file type or alternatively may correspond to a group of file types. The drive controller 410 sends the coded drive-speed corresponding to the file type index to the motor control

hardware registers 420. Based upon the coded drive-speed received, the motor control hardware registers may limit voltage to the drive 425, thereby regulating drive speed based on file type. For example, if the file type is audio CD, the motor control hardware registers may limit the drive voltage such that the drive rotates at approximately 500 RPMs. And if the file type is DVD-RAM, the motor control hardware registers may limit the drive voltage such that the drive rotates at approximately 4000 RPMs.

[0026] In the foregoing specification, the invention has been described with reference to specific exemplary embodiments thereof. It will, however, be evident that various modifications and changes may be made thereto without departing from the broader spirit and scope of the invention as set forth in the appended claims. The specification and drawings are, accordingly, to be regarded in an illustrative sense rather than a restrictive sense.
